## List of Corrections

# 1 Introduction

We introduce some auxiliary concepts and formulate general assumptions:

- A *bit stream* is an array containing elements of type `uint8_t`.  
A bit stream of length  $n$  contains  $8n$  bits.
- A bit stream is *valid* if the array is valid.
- A bit stream can be indexed both by its array indices and its *bit indices*.

Figure 1 shows the difference between array indices and bit indices in a bit stream. The two bit indices, 0 and 14, mark bit positions in the first and second array element, respectively.

Figure 1: Array indices and bit indices in a bit stream

- A *bit sequence* is a consecutive sequence of bits within a bit stream as represented in Figure 2.

Figure 2: A bit sequence within a bit stream

A bit sequence is given by the position of its first bit (a bit index in the bit stream) and its *length*, that is, the number of bits it contains.

- A bit sequence of length  $l$  that starts at bit index  $p$  is *valid* with respect to a bit stream of length  $n$  if the following conditions are satisfied

$$\begin{aligned} 0 &\leq p \leq 8n \\ 0 &\leq p + l \leq 8n \end{aligned}$$

- We assume that the C-types `unsigned int` and `int` have a width of 32 bits.

## 2 Primary Functions of Bitwalker

The core functionality of the bitwalker is expressed by the two functions `Bitwalker_Peek` and `Bitwalker_Poke`.

### 2.1 The Function `Bitwalker_Peek`

The function `Bitwalker_Peek` reads a bit sequence from a bit stream and converts it to an integer.

Its function signature reads as follows:

```
uint64_t Bitwalker_Peek(unsigned int Startposition,  
                        unsigned int Length,  
                        uint8_t Bitstream[],  
                        unsigned int BitstreamSizeInBytes);
```

#### Arguments

- `Startposition` is the bit index in the bit stream where the bit sequence starts.
- `Length` is the length of the bit sequence.
- `Bitstream` is the array which provides the bit stream.
- `BitstreamSizeInBytes` is the length of the array containing the bit stream.

#### Preconditions

The following preconditions shall hold for the function arguments:

- `Bitstream` is a valid array of length `BitstreamSizeInBytes`
- $\text{Length} \leq 64$  and
- $\text{Startposition} + \text{Length} \leq \text{UINT\_MAX}$ .

Note that additional constraints are implicitly expressed by the use of *unsigned* integer types.

#### Description

The function `Bitwalker_Peek` reads a bit sequence from a bit stream and converts it to a 64-bit unsigned integer.

The left most bit of the bit sequence is interpreted as the most significant bit. Thus, for a bit sequence  $(b_0, b_1, \dots, b_{n-1})$  the function returns the sum

$$b_0 \cdot 2^{n-1} + b_1 \cdot 2^{n-2} + \dots + b_{n-1} \cdot 2^0 = \sum_{i=0}^{n-1} b_i \cdot 2^{(n-1)-i} \quad (1)$$

If the bit sequence is not valid, then the function returns 0. This increases the robustness of the function.

## Complexity

The run time shall be linear in the length of the bit sequence.

## 2.2 The Function `Bitwalker_Poke`

The function `Bitwalker_Poke` converts an integer to a bit sequence and writes it into a bit stream. Its function signature reads as follows:

```
int Bitwalker_Poke(unsigned int Startposition,
                  unsigned int Length,
                  uint8_t Bitstream[],
                  unsigned int BitstreamSizeInBytes,
                  uint64_t Value);
```

## Arguments

- `Startposition` is the bit index in the bit stream where the bit sequence starts.
- `Length` is the length of the bit sequence.
- `Bitstream` is the array which provides the bit stream.
- `BitstreamSizeInBytes` is the length of the array containing the bit stream.
- `Value` is the integer which shall be converted into a bit sequence.

## Preconditions

The following preconditions shall hold for the function arguments:

- `Bitstream` is a valid array of length `BitstreamSizeInBytes`
- `Startposition + Length ≤ UINT_MAX`.

Note that additional constraints are implicitly expressed by the use of *unsigned* integer types.

## Description

The function `Bitwalker_Poke` converts a 64-bit unsigned integer to a bit sequence and writes it into a bit stream.

For  $0 \leq x$  exists a shortest sequences of 0 and 1  $(b_0, b_1, \dots, b_{n-1})$  such that

$$\sum_{i=0}^{n-1} b_i \cdot 2^{(n-1)-i} = x. \quad (2)$$

The function `Bitwalker_Poke` tries to store the sequence  $(b_0, b_1, \dots, b_{n-1})$  in the bit sequence of `Length` bits that starts at bit index `Startposition`.

The return value of `Bitwalker_Poke` depends on the following three cases:

- If the bit sequence is large enough to store the sequence  $(b_0, b_1, \dots, b_{n-1})$ , then `Bitwalker_Poke` returns 0.
- If `Length`  $< n$ , then the sequence  $(b_0, b_1, \dots, b_{n-1})$  cannot be stored and `Bitwalker_Poke` return  $-1$ .
- If the bit sequence is not valid, then `Bitwalker_Poke` returns  $-2$ .

## Complexity

The run time shall be linear in the length of the bit sequence.

### 2.3 Interaction of `Bitwalker_Peek` and `Bitwalker_Poke`

The functions `Bitwalker_Peek` and `Bitwalker_Poke` are inverse to each other.

### **3 Secondary Functions of Bitwalker**
